List of Acronyms and terminologies for non LIGO folks

1. aLIGO - Advanced laser interferometer gravitational-wave observatory.
2. O3 - Observing run 3, the third aLIGO run of gravitational-wave detection that began on April 1, 2019 and ended on March 28, 2020
3. H1 and L1 - Gravitational wave detector at Hanford and Livingston respectively
4. Glitch/Trigger - short duration events with high energy aka noise
5. Omega scans - Time-frequency spectrograms of noise events

Overview

1. Introduction to GravitySpy
2. Introduction to Fast scattering and Low frequency blips
3. Training the model
4. Old and new model output comparison

What is GravitySpy?

- It is an image recognition algorithm based on convolutional neural networks (CNN)
- Classifies transient noise at LIGO in 22 classes/labels
- <https://ldvw.ligo.caltech.edu/ldvw/gspySearch> web interface of GravitySpy
- Download the data in csv format for further analysis
- GravitySpy [paper](#)

Training set

- The algorithm is trained on time-frequency spectrograms of noise transients
- For each event, the training set contains 4 images of 0.5, 1, 2 and 4 secs.

- These 4 images are then concatenated to form a single image used for training.

Model details

- Number of layers: 5
 - 4 CNN layers and 1 fully connected Softmax layer.
- The output of softmax layer is:

$$o_c^i = \frac{e^{w_c^T x}}{\sum_{c=1}^C e^{w_c^T x}} \quad \text{for } i\text{th image, } c = 1 \text{ to } C, \text{ the number of classes}$$

- Loss function : Cross entropy

$$-\sum_{i=1}^N \sum_{c=1}^C y_c^i \log o_c^i \quad y^i \text{ denotes the binary label for sample } i.$$

- More details in this [paper](#)

Fast scattering

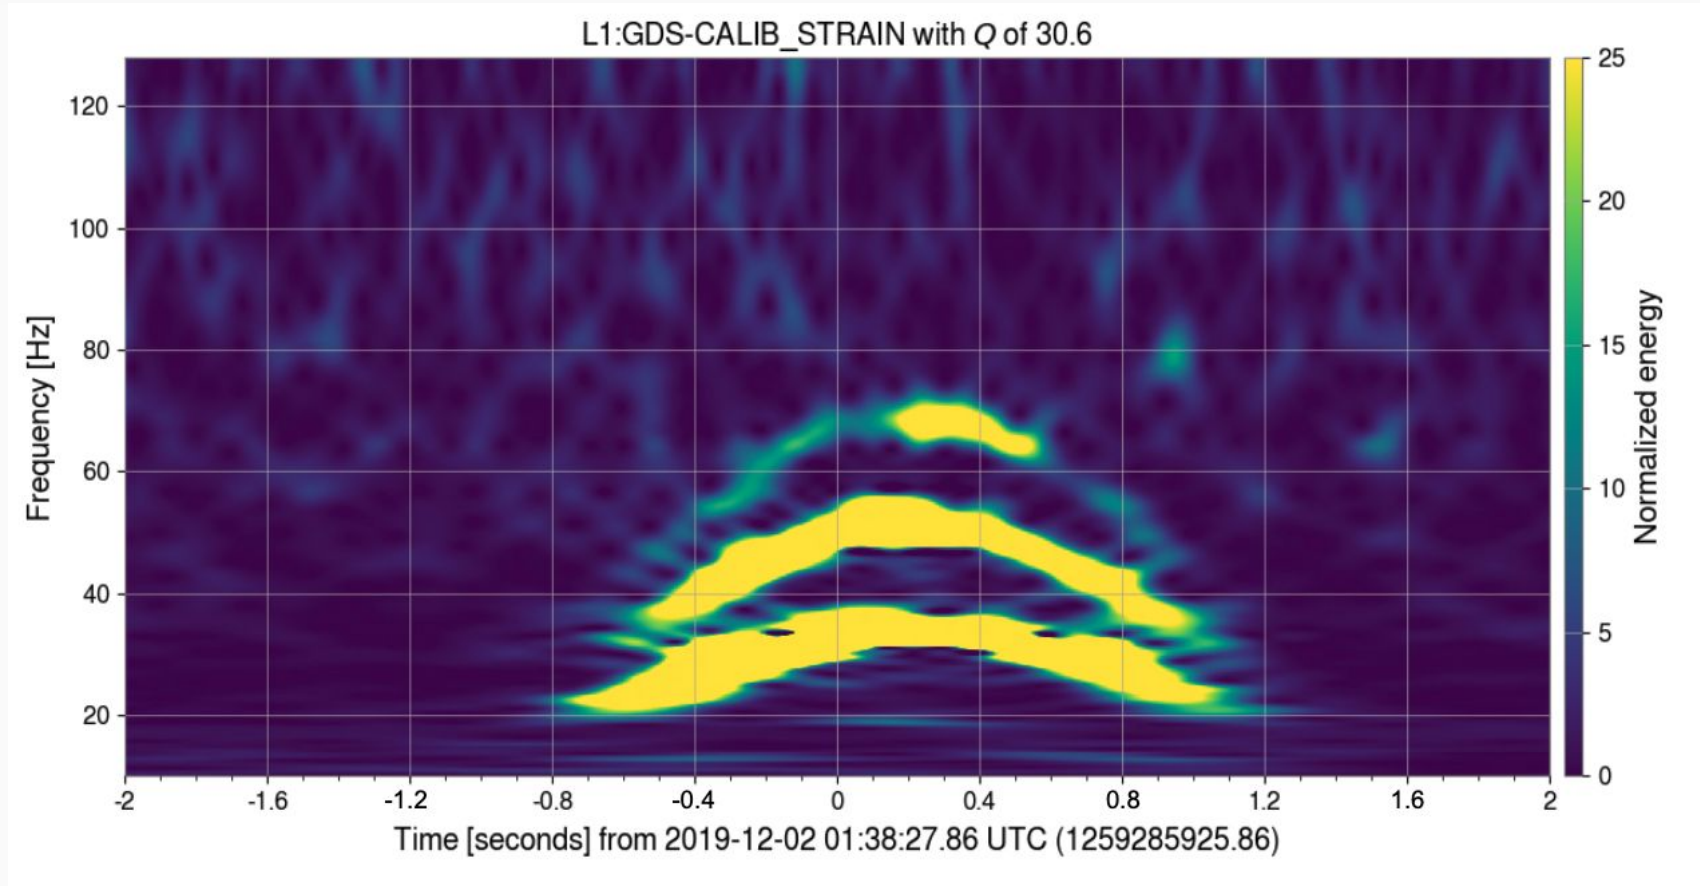

Short duration fast scattering arches

These triggers are currently classified as `Scattered_Light` or `Slow scattering` which is another population of scattering noise

Next slide shows an example of `Slow scattering`

Slow scattering

Blips and Low frequency blips

All four triggers assigned as Blips with confidence above 0.95 by the current GravitySpy model

They may have different origins due to different bandwidth

Blips

Low frequency blips

Training

- All training images taken from O3 classification are with confidence above 0.95
- For fast scattering, 400 triggers currently classified as scattering with Q-value between 8 and 14
- For low frequency blips, 630 Blips with peak frequency between 10 and 50 Hz
- 150 slow scattering (Scattered_Light) images
- 300 Tomte
- Removed None_of_the_Above
- Valid acc: 0.988, Training acc: 0.999

- Total 23 classes
- Addition of two new classes
 - Fast scattering
 - Low frequency blips
- Removed None of the above glitch category

```

Testing the model

- Is the model recognizing fast scattering?
- Is the model recognizing low frequency blips?
- Does it affect other glitch categories?

Testing on Fast scattering and Low frequency Blips

- Randomly sample 100 triggers currently classified as **Scattering** at L1 by GravitySpy between June, 1, 2019 and June, 30, 2019, with q between 8 and 14
- The new model classified all of them as **Fast Scattering**
- Random visual inspection of the omega scans of these 100 triggers to confirm correct classification
- These scans are stored [here](#)
- Randomly sampled 79 triggers currently classified as **Blip** at L1 by GravitySpy between Feb, 1, 2020 and Mar, 1, 2020 with peak frequency between 10 and 50 Hz
- The new model classified 78 of these as **Blip_Low_Frequency** and 1 as **Tomte**
- Visually inspected the scans
- These scans are stored [here](#)

Fast_Scattering

Blip_Low_Frequency

Testing on O3 sample

- Relabelled 20% of the O3 gravity spy triggers at L1 and H1 with the new model
- Some of the questions we can ask are:
 - Is there a big change in confidence assigned to the triggers by the new model?
 - What percentage of triggers are labelled with a different classification?
 - For triggers assigned a different class, what is the distribution of new labels?
 - What glitch classes were assigned to these new labels by the original model?
 - Does the change make sense?

Confidence comparison

Change in confidence assigned to the glitches is minimal

Change in class labels

O3 classification by the new model wrt old model at H1

O3 classification by the new model wrt old model at L1

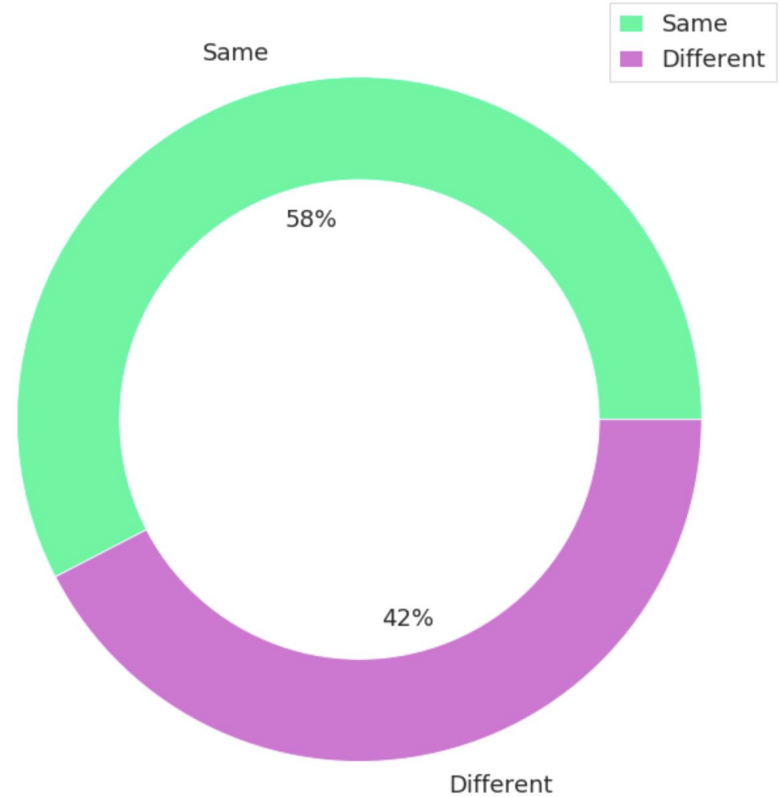

Change in class labels

O3 classification by the new model wrt old model at H1

O3 classification by the new model wrt old model at L1

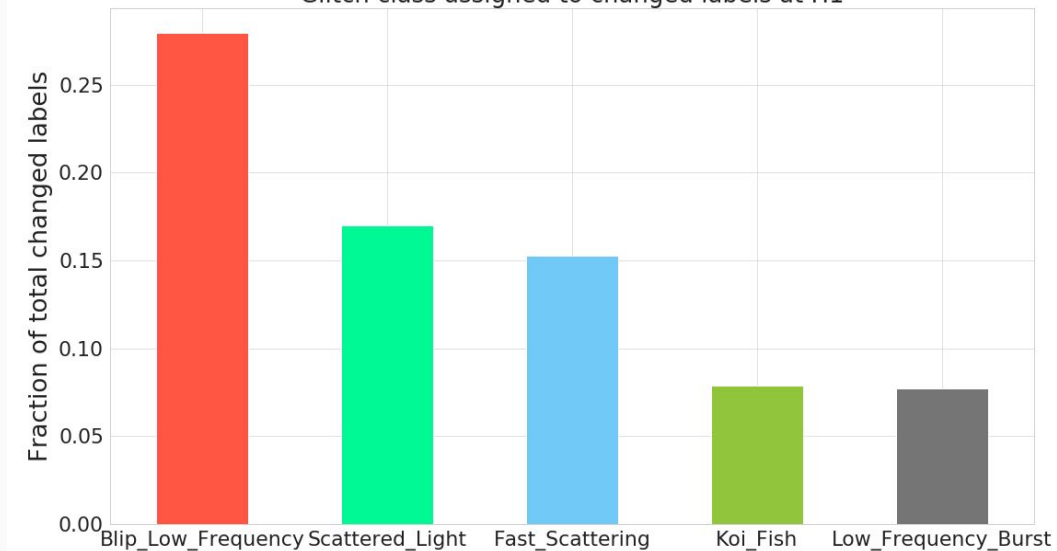

Distribution of new labels at H1

O3 classification by the new model wrt old model at H1

Glitch class assigned to changed labels at H1

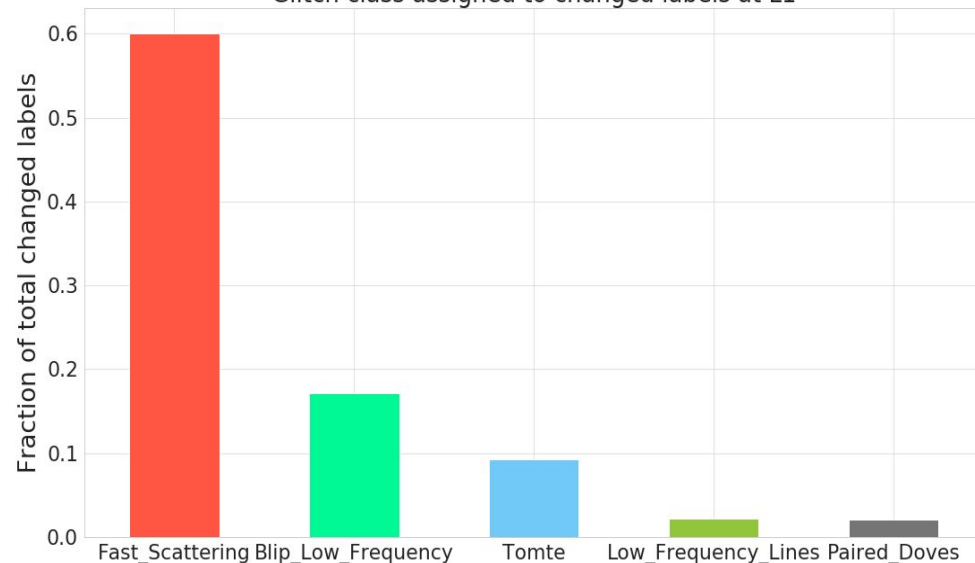

Glitch class assigned to these triggers

Distribution of new labels at L1

O3 classification by the new model wrt old model at L1

Glitch class assigned to changed labels at L1

Glitch class assigned to these triggers

Previous classification of Fast scattering

H1

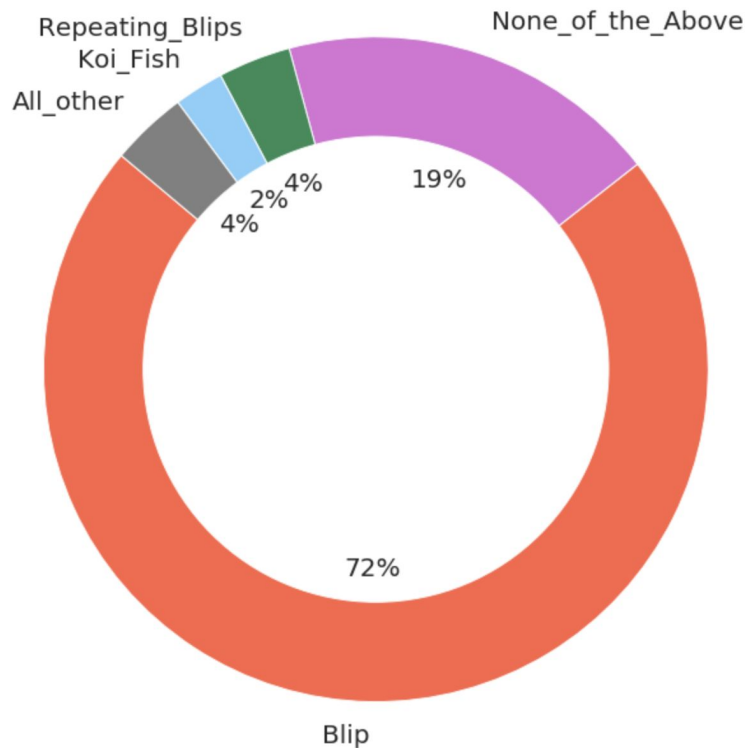

L1

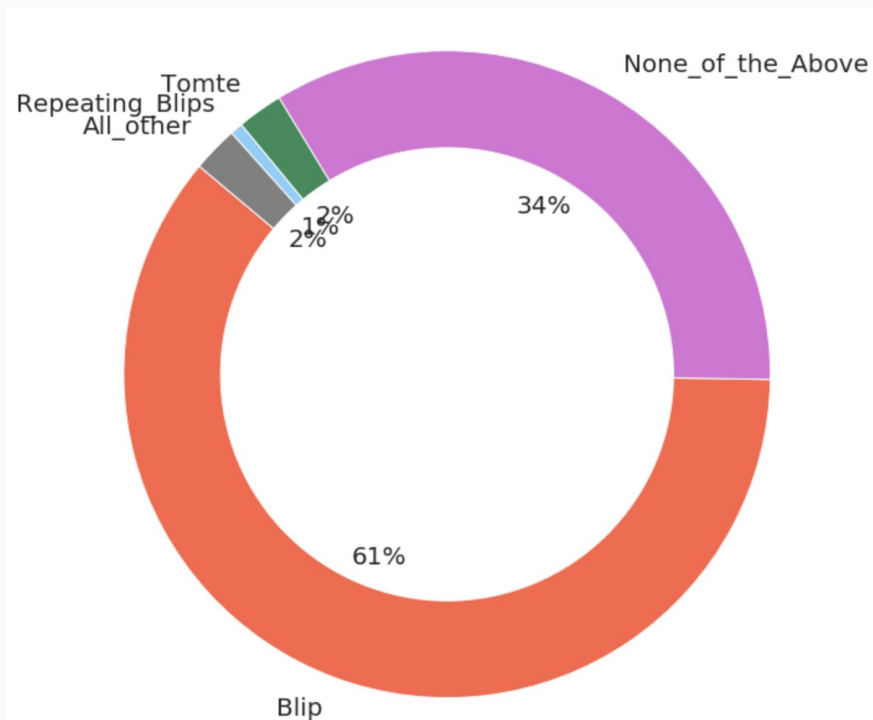

Previous classification of low frequency blips

H1

L1

- New model to identify
 - Fast scattering
 - Low frequency blips
- It should not affect other classes

Heatmap on next two slides

- We consider those glitches that are assigned a different glitch class by the new model
- For each old label we look at the distribution of new labels assigned

- A fraction of Extremely_Loud triggers classified as scattering.
- [Omega scans](#) show those triggers are indeed scattered light noise.

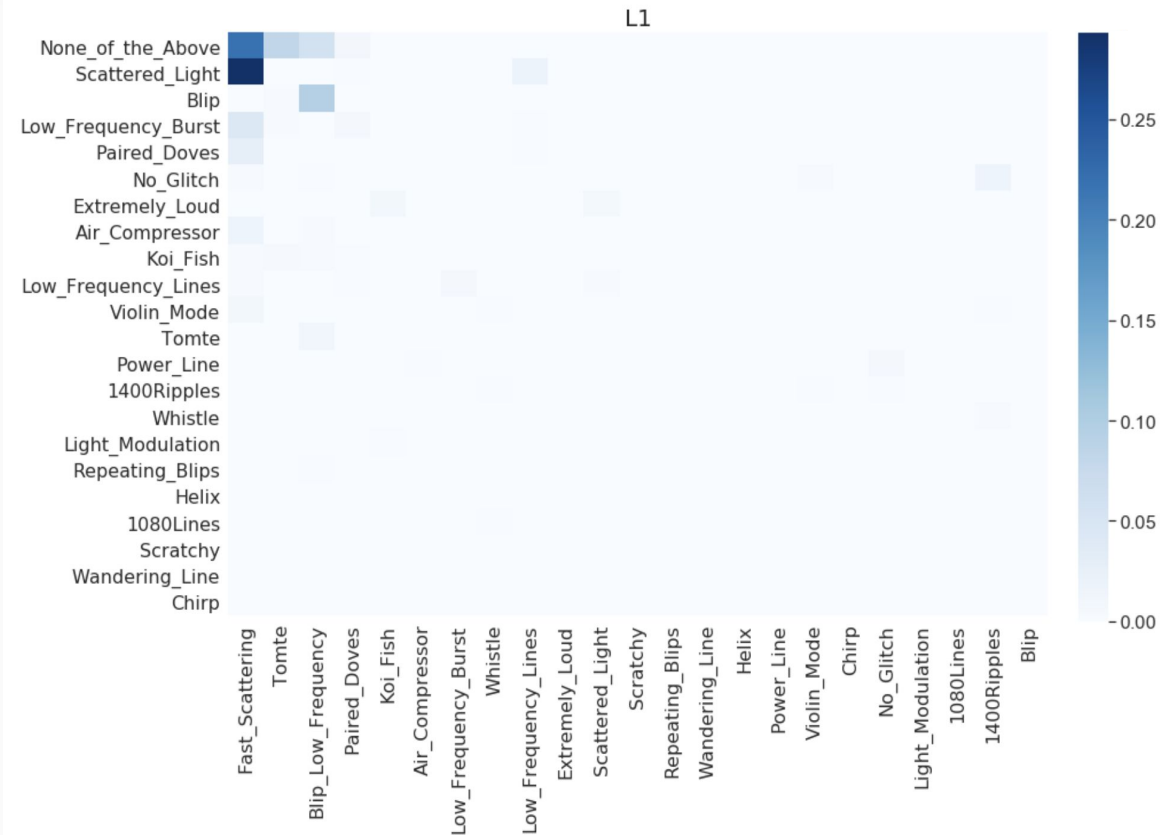

Old classification

New classification

- The H1 and L1 heatmap shows that the new model does not meddle with the old glitch classes.
- Correctly recognizes **Scattered_light** at H1 misclassified as **Extremely_Loud** by the older model

Old classification

New classification

Next steps

1. Update the model on [Ligo-dv-web](#) (ldvw) and on the GravitySpy SQL Table (Done)
2. Update the model and the data on the GravitySpy [repository](#) (Done)
3. Separate training set for L1 and H1?

Thank you
